

Problem Statement: Geometry Calculator Using Python Module

Develop a **menu-driven Python application** that demonstrates the use of **User-Defined Modules** and **Functions**.

Requirements

You are required to create a Python module named **twodfigures.py** that contains functions to perform the following calculations for different two-dimensional shapes:

- **Triangle**
 - Calculate Area
 - Calculate Perimeter
- **Circle**
 - Calculate Area
 - Calculate Circumference (Perimeter)
- **Square**
 - Calculate Area
 - Calculate Perimeter
- **Rectangle**
 - Calculate Area
 - Calculate Perimeter

Create another Python file named **operations.py** that imports the twodfigures module and performs the following tasks:

1. Display a menu for selecting one of the following figures:
 - Square
 - Circle
 - Triangle
 - Rectangle
2. Based on the user's choice, ask for the required dimensions of the selected figure.
 - Example:
 - Circle → Radius
 - Square → Side
 - Rectangle → Length and Breadth
 - Triangle → Three sides (for perimeter) and Base & Height (for area)
3. Display a second menu to choose the required operation:

- Area
- Perimeter

4. Call the appropriate function from the **twodfigures** module based on the user's selections.
5. Display the calculated result in a user-friendly format.
6. Allow the user to perform multiple calculations until they choose to exit the application.
